

Interrupt

By,
S.Angel Deborah

Introduction

- **Interrupt** is the method of creating a temporary halt during program execution and allows peripheral devices to access the microprocessor.
- The microprocessor responds to that interrupt with an **ISR** (Interrupt Service Routine), which is a short program to instruct the microprocessor on how to handle the interrupt.

Classification

Hardware Interrupts

- Hardware interrupt is caused by any peripheral device by sending a signal through a specified pin to the microprocessor.
- The 8086 has two hardware interrupt pins, i.e. NMI and INTR.
- NMI is a non-maskable interrupt and INTR is a maskable interrupt having lower priority.
- One more interrupt pin associated is INTA called interrupt acknowledge.

NMI

- It is a single non-maskable interrupt pin (NMI) having higher priority than the maskable interrupt request pin (INTR).
- When this interrupt is activated, these actions take place –
 - Completes the current instruction that is in progress.
 - Pushes the Flag register values on to the stack.
 - Pushes the CS (code segment) value and IP (instruction pointer) value of the return address on to the stack.
 - IP is loaded from the contents of the word location 00008H.
 - CS is loaded from the contents of the next word location 0000AH.
 - Interrupt flag and trap flag are reset to 0.

INTR

- The INTR is a maskable interrupt because the microprocessor will be interrupted only if interrupts are enabled using set interrupt flag instruction.
- It should not be enabled using clear interrupt Flag instruction.
- The INTR interrupt is activated by an I/O port.
- If the interrupt is enabled and NMI is disabled, then the microprocessor first completes the current execution and sends '0' on INTA pin twice.
- The first '0' means INTA informs the external device to get ready and during the second '0' the microprocessor receives the 8 bit, say X, from the programmable interrupt controller.

INTR

- These actions are taken by the microprocessor –
 - First completes the current instruction.
 - Activates INTA output and receives the interrupt type, say X.
 - Flag register value, CS value of the return address and IP value of the return address are pushed on to the stack.
 - IP value is loaded from the contents of word location $X \times 4$
 - CS is loaded from the contents of the next word location.
 - Interrupt flag and trap flag is reset to 0

Software Interrupts

- Some instructions are inserted at the desired position into the program to create interrupts.
- These interrupt instructions can be used to test the working of various interrupt handlers

INT- Interrupt instruction with type number

- It is 2-byte instruction.
- First byte provides the op-code and the second byte provides the interrupt type number.
- There are 256 interrupt
- Its execution includes the following steps –
 - Flag register value is pushed on to the stack.
 - CS value of the return address and IP value of the return address are pushed on to the stack.
 - IP is loaded from the contents of the word location 'type number' \times 4
 - CS is loaded from the contents of the next word location.
 - Interrupt Flag and Trap Flag are reset to 0
 - t types under this group.

INT- Interrupt instruction with type number

- The starting address for type0 interrupt is 000000H, for type1 interrupt is 00004H similarly for type2 is 00008H andso on. The first five pointers are dedicated interrupt pointers. i.e.
 -
 - **TYPE 0** interrupt represents division by zero situation.
 - **TYPE 1** interrupt represents single-step execution during the debugging of a program.
 - **TYPE 2** interrupt represents non-maskable NMI interrupt.
 - **TYPE 3** interrupt represents break-point interrupt.
 - **TYPE 4** interrupt represents overflow interrupt.
- The interrupts from Type 5 to Type 31 are reserved for other advanced microprocessors, and interrupts from 32 to Type 255 are available for hardware and software interrupts.

INT 3-Break Point Interrupt Instruction

- It is a 1-byte instruction having op-code is CCH.
- These instructions are inserted into the program so that when the processor reaches there, then it stops the normal execution of program and follows the break-point procedure.
- Its execution includes the following steps –
 - Flag register value is pushed on to the stack.
 - CS value of the return address and IP value of the return address are pushed on to the stack.
 - IP is loaded from the contents of the word location $3 \times 4 = 0000\text{CH}$
 - CS is loaded from the contents of the next word location.
 - Interrupt Flag and Trap Flag are reset to 0

INTO - Interrupt on overflow instruction

- It is a 1-byte instruction and their mnemonic **INTO**.
- The op-code for this instruction is CEH.
- As the name suggests it is a conditional interrupt instruction, i.e. it is active only when the overflow flag is set to 1 and branches to the interrupt handler whose interrupt type number is 4.
- If the overflow flag is reset then, the execution continues to the next instruction.
- Its execution includes the following steps –
 - Flag register values are pushed on to the stack.
 - CS value of the return address and IP value of the return address are pushed on to the stack.
 - IP is loaded from the contents of word location $4 \times 4 = 00010H$
 - CS is loaded from the contents of the next word location.
 - Interrupt flag and Trap flag are reset to 0

Priority

- Divide Error, INT n, INTO
- NMI
- INTR
- Single-step
